

ABSTRACT

The method is used to control a function (f) executable by various software products (4a, 4b, 6a, 6b) by means of commands (Pa-Pd) specific to the respective software products and each capable of having at least one option, the software products being installed in at least one machine (2a, 2b) of a computer system (10). Said method consists of defining in an abstract class an abstract method for the function (f), of defining a common command (P0) that includes arbitrary symbols corresponding to the parameters of the abstract method, of creating at least one driver (52) for implementing the abstract method in a machine, and having the driver execute one of the specific commands with options equivalent to the options of the common command.
